Multi-dimensional Quadrature

In order to find an alternative way to approximate the $d$-dimensional integral

$$F_d := \int_{[0,1]^d} u(x_1, \ldots, x_d) \, d(x_1, \ldots, x_d)$$

we use a regular $d$-dimensional grid of step size $h = 2^{-n}$ stored in an array with indices in $[0, 2^n]^d$.

We don’t want to be bothered with special boundary treatment so we simplify this task assuming our function is 0 on the boundary, i.e.

$$\forall \mathbf{x} = [x_1, \ldots, x_d]^T : \exists j \text{ such that } (x_j = 0 \lor x_j = 1) \Rightarrow u(\mathbf{x}) = 0$$

In the next step we compute the $d$-dimensional hierarchical surpluses:

```
loop j = 1, \ldots, d over the dimensions
  loop over all 1d subgrids discretizing spatial direction j
    (fix all coordinates except $x_j$, what you’ll get is a 1d array
     of grid points like on worksheet 4 — for $d = 2$ this comes down
to processing all rows and all columns once)
  Compute 1d surpluses in dimension $j$ (in place) for each subarray
```

Once we have the surpluses $v_{\ell,i}$ (indexing with level $\ell$ and point index $i$) as introduced in the lecture) we only need to multiply them with the volume of the associated pagoda and sum everything up. The volume of the pagoda associated with grid point $x_{\ell,i}$ is $2^{-|\ell|}$.  

1. Implement this method!
   For $d = 2$ and $n = 3$ this can be done easily in a spreadsheet (using copy and paste is not only ok but also encouraged for thorough understanding).

2. Let

$$u(x_1, x_2) = 16x_1(1 - x_1)x_2(1 - x_2) = \left(1 - 4(x_1 - \frac{1}{2})^2\right) \cdot \left(1 - 4(x_2 - \frac{1}{2})^2\right).$$

Write the summed up volumes in descending order (compute with your program or derive from results of worksheet 5). Imagine $n$ to be large.

How many volumes are at least needed to approximate the integral ($4/9$) with an absolute error not larger than $1/144$ (this choice is not random, it will give you nice results).

3. Spot and draw the used grid points in the unit square!
