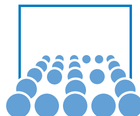
Fundamental Algorithms

Chapter 6: Parallel Algorithms – The PRAM Model

Dirk Pflüger

Winter 2010/11



Example: Parallel Searching

Definition (Search Problem)

Input: a set A of n elements $\in \mathcal{A}$, and an element $x \in \mathcal{A}$.
Output: The (smallest) index $i \in \{1, \ldots, n\}$ with $x = A[i]$.

An immediate solution:

- use n processors
- on each processor: compare x with $A[i]$
- return matching index/indices i

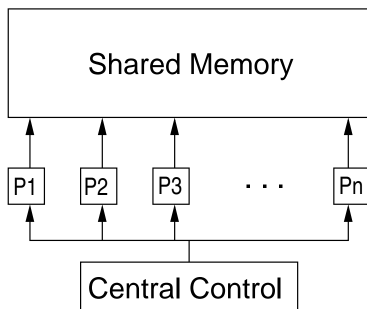
Simple Parallel Searching

```
ParSearch(A:Array[1..n], x:Element) : Integer {
    for i from 1 to n do in parallel {
        if x = A[i] then return i;
    }
}
```

Discussion:

- Can all n processors access x simultaneously?
  $\rightarrow$ **exclusive** or **concurrent** read
- What happens if more than one processor finds an x?
  $\rightarrow$ **exclusive** or **concurrent** write (of multiple returns)

The PRAM Models



Concurrent or Exclusive Read/Write Access:

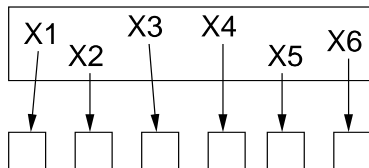
EREW exclusive read, exclusive write

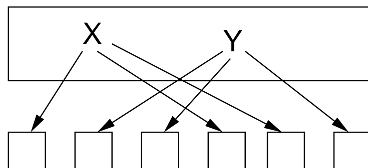
CREW concurrent read, exclusive write

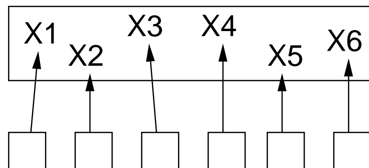
ERCW exclusive read, concurrent write

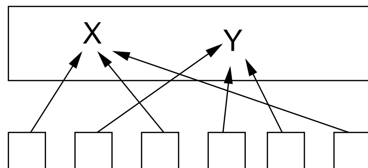
CRCW concurrent read, concurrent write

Exclusive/Concurrent Read and Write Access

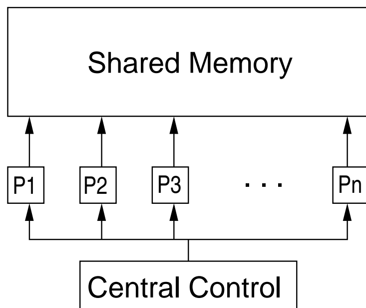








The PRAM Models (2)



SIMD

- Underlying principle for parallel hardware architecture: strict single instruction, multiple data (SIMD)

⇒ All parallel instructions of a parallelized loop are performed synchronously (applies even to simple if-statements)

Parallel Search on an EREW PRAM

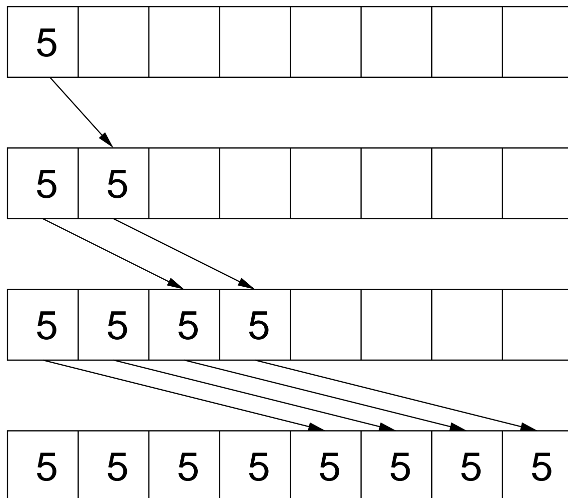
ToDos for exclusive read and exclusive write:

- avoid exclusive access to x
  $\Rightarrow$ replicate x for all processors ("broadcast")
- determine smallest index of all elements found:
  $\Rightarrow$ determine minimum in parallel

Broadcast on the PRAM:

- copy x into all elements of an array X[1..n]
- note: each processor can only produce one copy per step

Broadcast on the PRAM – Copy Scheme



Broadcast on the PRAM – Implementation

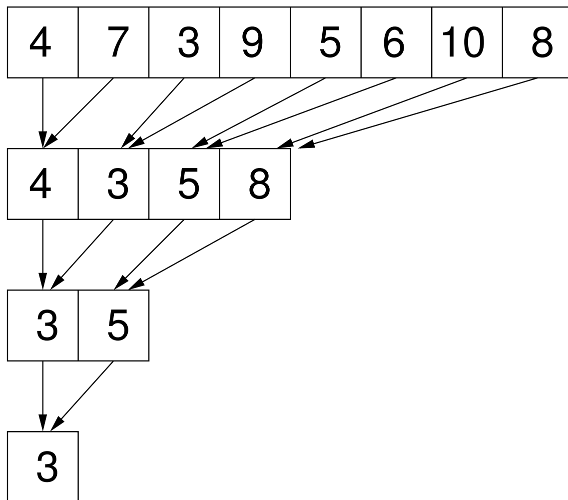
```
BroadcastPRAM( x:Element, A:Array[1..n]) {
    // n assumed to be 2^k
    // Model: EREW PRAM

    A[1] := x;
    for i from 0 to k-1 do
        for j from 2^i+1 to 2^(i+1) do in parallel {
            A[j] := A[j-2^i];
        }
}
```

Complexity:

- $T(n) = \Theta(\log n)$ on $\frac{n}{2}$ processors

Minimum Search on the PRAM – “Binary Fan-In”



Minimum on the PRAM – Implementation

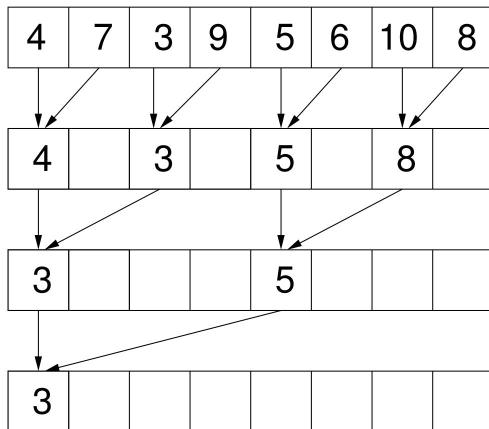
```
MinimumPRAM( A:Array[1..n]) : Integer {
   // n assumed to be 2^k
   // Model: EREW PRAM

   for i from 1 to k do  {
      for j from 1 to n/(2^i) do in parallel
         if A[2j-1] > A[2j]
         then A[j] := A[2j];
         else A[j] := A[2j-1];
         end if;
   }
   return A[1];
}
```

Complexity: $T(n) = \Theta(\log n)$ on $\frac{n}{2}$ processors

“Binary Fan-In” (2)

Comment Concerned about synchronous if-statement (guaranteed by SIMD assumptions)?
$\Rightarrow$ Modifiy stride!



Searching on the PRAM – Parallel Implementation

```
SearchPRAM( A:Array[1..n], x:Element) : Integer {
    // n assumed to be 2^k
    // Model: EREW PRAM

    BroadcastPRAM(x, X[1..n]);

    for i from 1 to n do in parallel {
        if A[i] = X[i]
        then X[i] := i;
        else X[i] := n+1;   // (invalid index)
        end if;
    }

    return MinimumPRAM(X[1..n]);
}
```

The Prefix Problem

Definition (Prefix Problem)

Input: an array A of n elements a_i.
Output: All terms $a_1 \times a_2 \times \cdots \times a_k$ for $k = 1, \ldots, n$.

$\times$ may be any associative operation.

Straightforward serial implementation:

```
Prefix( A:Array[1..n]) {
   // in-place computation:
   for i from 2 to n do {
         A[i] := A[i-1]*A[i];
   }
```

The Prefix Problem – Divide and Conquer

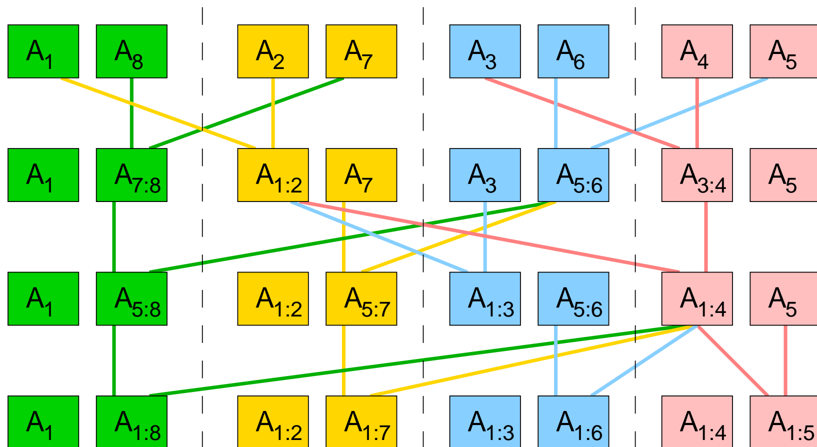
Idea:

1. compute prefix problem for $A_1, \ldots, A_{n/2}$
   $\rightarrow$ gives $A_{1:1}, \ldots, A_{1:n/2}$
2. compute prefix problem for $A_{n/2+1}, \ldots, A_n$
   $\rightarrow$ gives $A_{n/2+1:n/2+1}, \ldots, A_{n/2+1:n}$
3. multiply $A_{n/2}$ with $A_{n/2+1:n/2+1}, \ldots, A_{n/2+1:n}$
   $\rightarrow$ gives $A_{1:n/2+1}, \ldots, A_{1:n}$

Parallelism:

- steps 1 and 2 can be computed in parallel (divide)
- all multiplications in step 3 can be computed in parallel
- recursive extension leads to parallel prefix scheme

Parallel Prefix Scheme on a CREW PRAM



Parallel Prefix – CREW PRAM Implementation

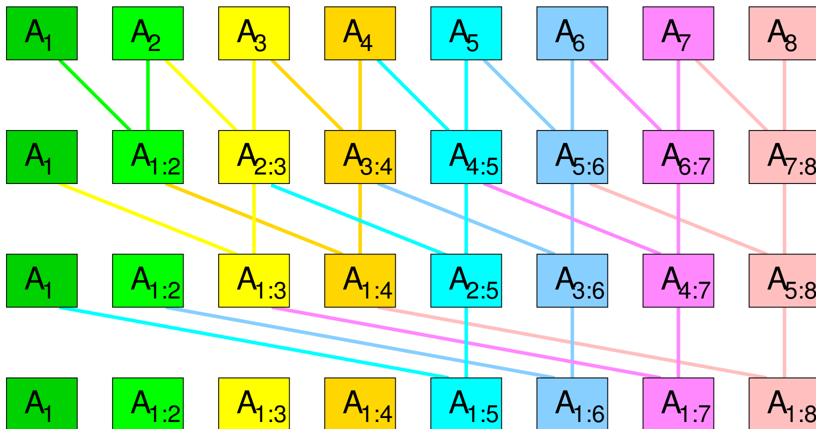
```
PrefixPRAM( A:Array[1..n]) {
  // n assumed to be 2^k
  // Model: CREW PRAM (n/2 processors)

  for l from 0 to k-1 do
     for p from 2^l by 2^(l+1) to n do in parallel
        for j from 1 to 2^l do in parallel {
           A[p+j] := A[p]*A[p+j];
        }
}
```

Comments:

- p- and j-loop together: n/2 multiplications per l-loop
- concurrent read access to A[p] in the innermost loop

Parallel Prefix Scheme on an EREW PRAM



Parallel Prefix – EREW PRAM Implementation

```
PrefixPRAM( A:Array[1..n]) {
  // n assumed to be 2^k
  // Model: EREW PRAM (n−1 processors)

  for l from 0 to k−1 do
     for j from 2^l+1 to n do in parallel {
        tmp[j] := A[j−2^l];
        A[j] := tmp[j]∗A[j];
     }
}
```

Comment:

- all processors execute tmp[j] := A[j-2ˆl] before multiplication!
